Did you know that there are more worms than people on planet earth??

Wriggling…
Writhing…Wow!

There are many different types of worm infection.

Worm infections cause severe health problems, particularly in children. The World Health Organisation now agrees that these infections trap countries in poverty because of their indirect effect on economic growth.

Along with your gastrointestinal tract, worms can live in many different places in your body including the brain, liver, lungs and lymphatic system.

Interestingly different people respond differently to infection, even if they are infected by the same parasite. Non-wormy people can get rid of their worm infection, but some wormy people go on to have long lasting chronic infections, making them very ill.

Here in Manchester we study the immune system to try and understand the reason behind these different responses to infection.

Our research has shown that...

1 billion people worldwide are affected by gut helminth (worm) infections.

• Our immune response to the rescue

Our work has made lots of discoveries about how our immune system works during infection. We now know which kind of immune response promotes resistance to infection. We also know that you need a very quick response by immune cells called dendritic cells to make sure that the immune response gets moving!

• Mucus fights back!

When worms infect the gut, the body makes more mucus which helps to expel the worm.

• Whipworm spends its whole life wriggling to stay where it is in the gut. It continually burrows into the gut lining against the natural renewal process, a bit like running down an up escalator. Our bodies can increase the speed of the ‘escalator’ and beat the worm at its own game! Eventually the worm can’t keep up and gets pushed out into the faeces.

• Whipworms are perfectly adapted to live in the gut environment. When worm eggs are eaten, the eggs travel down the gut to the large intestine. The large intestine is full of bacteria and as soon as the eggs sense the bacteria they start to hatch.

• A wormy response to infection has a lot of similarities to severe Crohn’s disease. This may help us understand why treatment of Crohns’ patients with worm eggs actually makes them feel better!
